

Practical Distributed Authorization

Ankur Taly, Google Inc.
ataly@google.com

Two day course at the 2016 International School on Foundations of Security Analysis and Design, Bertinoro, Italy (Aug. 29 - Sep. 2)

Internet of Things (IoT)

Physical devices made accessible over the network

Exciting new possibilities!

img_source: http://www.ti.com/llds/media/images/wireless_connectivity/50BillionThings.png

Internet of Things Security

Goldmine for the bad guys

Scary new possibilities!

How the 'Internet of Things' could be fatal

Harriet Taylor | @Harri8t | Friday, 4 Mar 2016 | 1:57 PM ET

This is really scary!

Live feed from an airplane hangar in Norway!!

Found using `shodan.io` --- a search engine for finding devices (IoT), e.g., routers, servers, cameras, SCADA systems, HVAC systems etc.

source: <http://img.wonderhowto.com/img/original/32/45/63534020036048/0/635340200360483245.jpg>

Securing IoT

Naming and Authentication

How do devices name and identify each other during any interaction?

Delegation

How do users delegate devices to act on their behalf ?

Access control

How are access control policies defined?

Securing IoT

Naming and Authentication

How do devices name and identify each other during any interaction?

Delegation

How do users delegate devices to act on their behalf ?

Access control

How are access control policies defined?

This is in essence the problem of authorization in distributed systems

Authorization in distributed systems

Old problem with decades of amazing research

But, new hype around it (courtesy IoT)

Course overview

- Explore existing ideas and techniques in distributed authorization
- Evaluate their applicability to IoT and large, open distributed systems
- Develop the applications in the context of the “Vanadium” framework developed at Google Inc.

Agenda

Today

- Foundations of distributed authorization
- Authorization requirements for large distributed systems (e.g., IoT)
- Overview of the Vanadium authorization model

Tomorrow

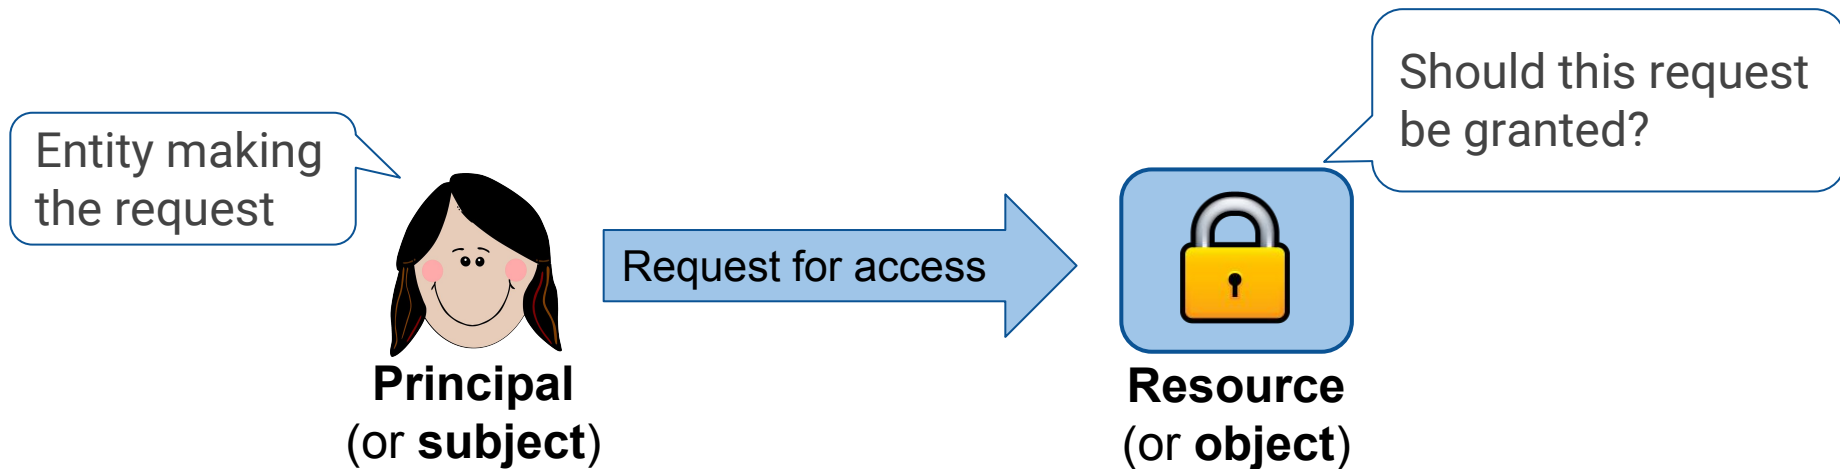

- Access control policies in Vanadium
- Privacy, discovery and authentication for Vanadium

Fundamentals of Distributed Authorization

Authorization

Fundamental problem in computer security that deals with whether a request to access a resource must be granted

Example: Door lock

Request is authorized only if the entered access code is valid

Example: Web login

Alice

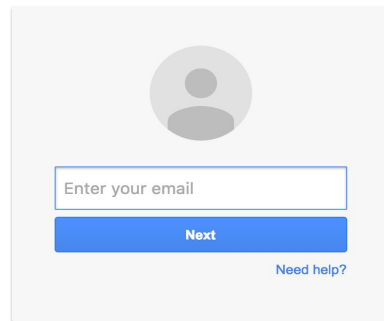

Username: alice
Password: *****

Request for access

One account. All of Google.

Sign in to continue to Gmail

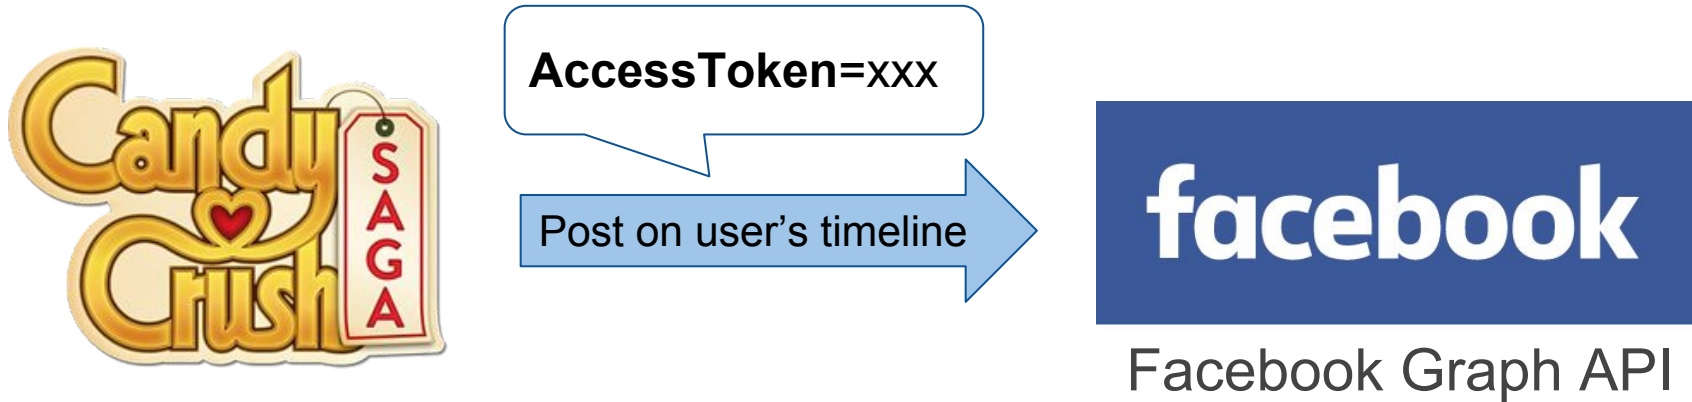

The login form features a grey circular profile icon placeholder at the top. Below it is a text input field with the placeholder text "Enter your email". Underneath the input field is a prominent blue button labeled "Next". At the bottom right of the form area, there is a small blue link that says "Need help?".

[Create account](#)

Login page grants access to **Google properties** (e.g., Gmail) only if the entered password is valid

Example where principal is non-user

Facebook API allows access to user's profile only if provided access token is valid and has the appropriate permissions

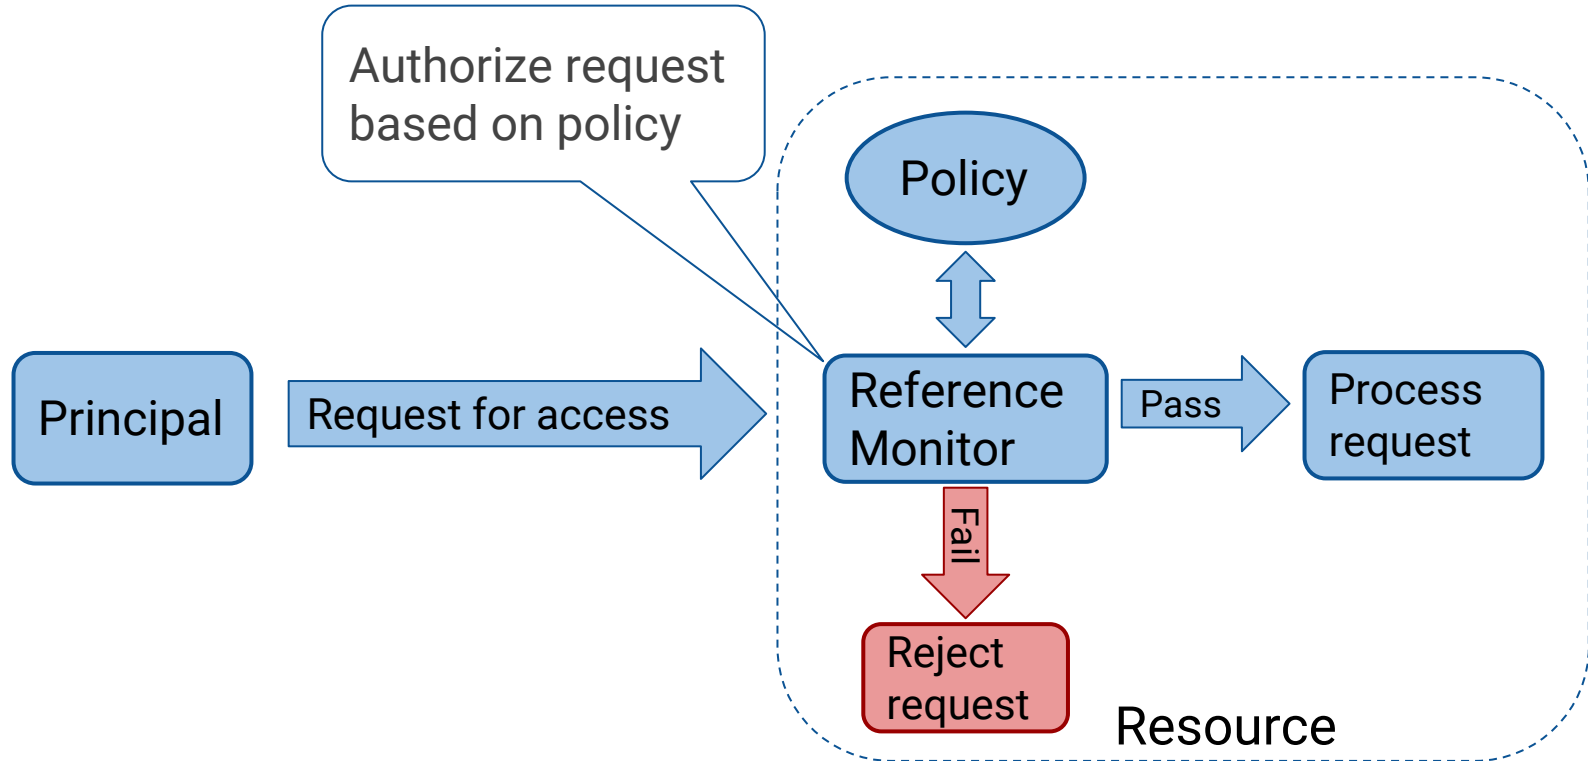

Principals

Entity making the request, can be:

- user
- device
- application
- browser tab
- or some combination of the above

Granularity varies across systems

Authorization model

Reference monitor (in closed systems)

Authentication + Access control

Authentication: Identify the principal making the request

- as a username, email, accountID, etc.

Access control: check if the identified principal is allowed by the policy

	file1	file2	file3
Alice	r	r	rwX
Bob	rw		x
Carol	rw	rw	x

Access control matrix
[Lampson, 1971]

Distributed authorization

Authorization is much more complicated in large, open, distributed systems such as the [Web](#), [Internet-of-Things \(IoT\)](#)

- No relationship between reference monitor and principal prior to request
 - may have to rely on third-parties for issuing and/or validating credentials
- Access control policies may be distributed
- The resource itself may be distributed
- Communication channels cannot be trusted

Delegation of authority and trust is essential

Example: >21 age check

Relying on a government (third-party) issued ID for verifying age > 21

Example: Third-party authentication

Alice

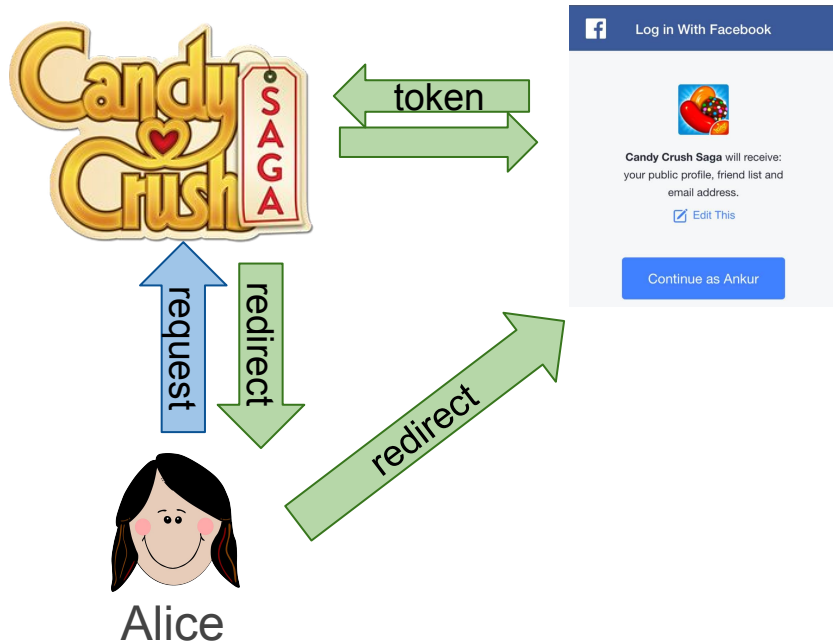

Problem

CandyCrush wants to service a request from Alice

But, it doesn't know how to authenticate Alice

How does CandyCrush authorize a request from Alice?

Example: Third-party authentication

Solution

Both CandyCrush and Alice have a relationship with Facebook

CandyCrush redirects Alice to Facebook and request an OAuth2 access token

It uses the token to obtain Alice's profile information at Facebook

Example: Streaming videos on a TV

Problem

Alice wants to stream a video from her Video server to her TV

Video service has a relationship with Alice but NOT with Alice's TV

How does the Video service authorize a request from Alice's TV?

Example: Stream a video on a TV

Solution

Alice authenticates the TV and hands it a credential to access the video service

TV presents this credential to the video service proving that it is authorized by Alice

Credentials-based authorization

- Authorization is based on credentials bound to the principal specifying
 - characteristics of the principal, e.g., identity, role, etc.
 - some other aspect of system state, e.g., time, location, etc.

Access control problem: Verify that a set of credentials C satisfy a policy P in the context of a request r

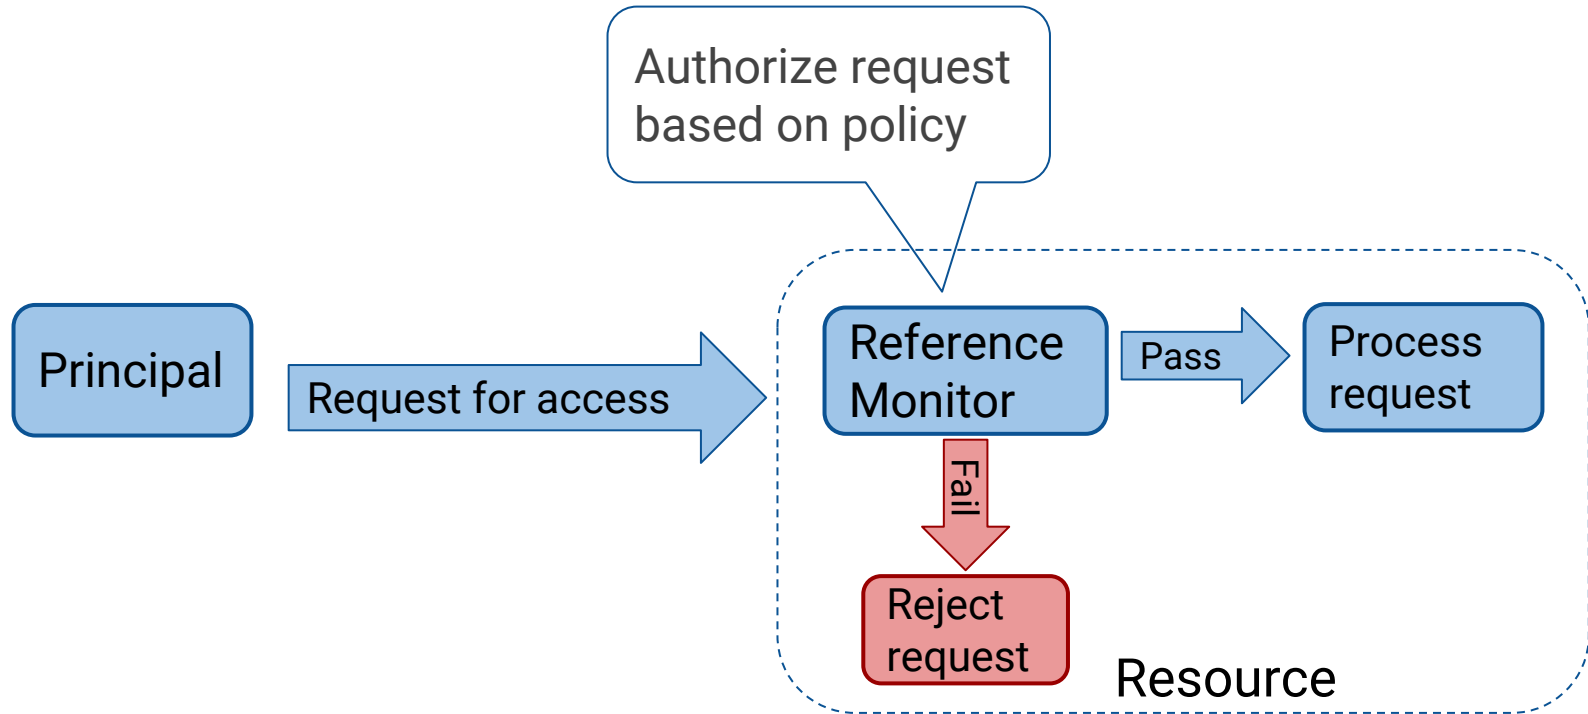

Credentials-based authorization

- Authorization is based on credentials bound to the principal specifying
 - characteristics of the principal, e.g., identity, role, etc.
 - some other aspect of system state, e.g., time, location, etc.

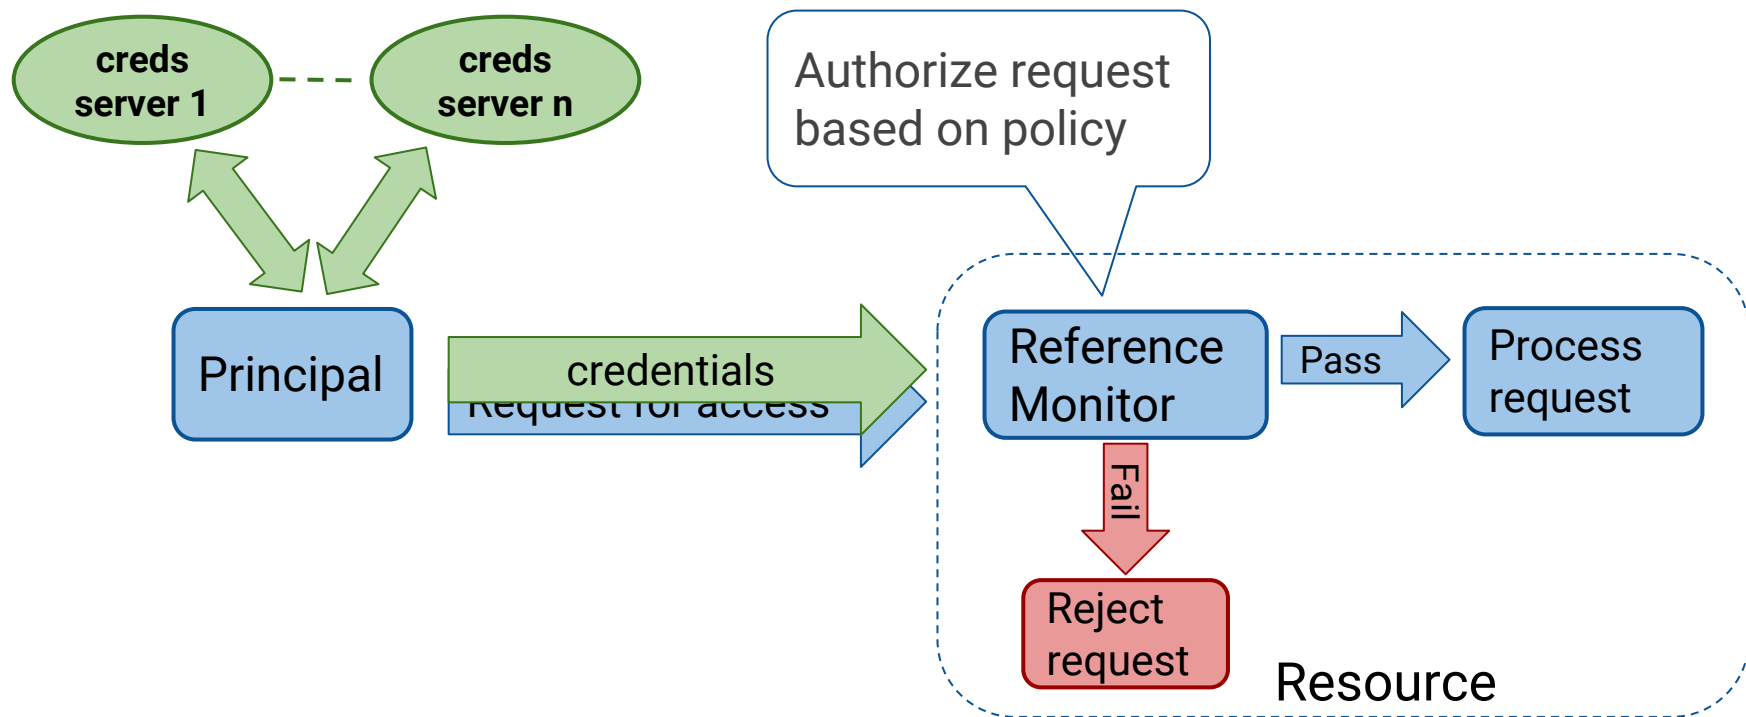

Access control problem: Verify that a set of credentials C satisfy a policy P in the context of a request r

- Different credential issuers are trusted for different purposes
- Credentials are either:
 - presented by the principal OR
 - gathered by the reference monitor on demand

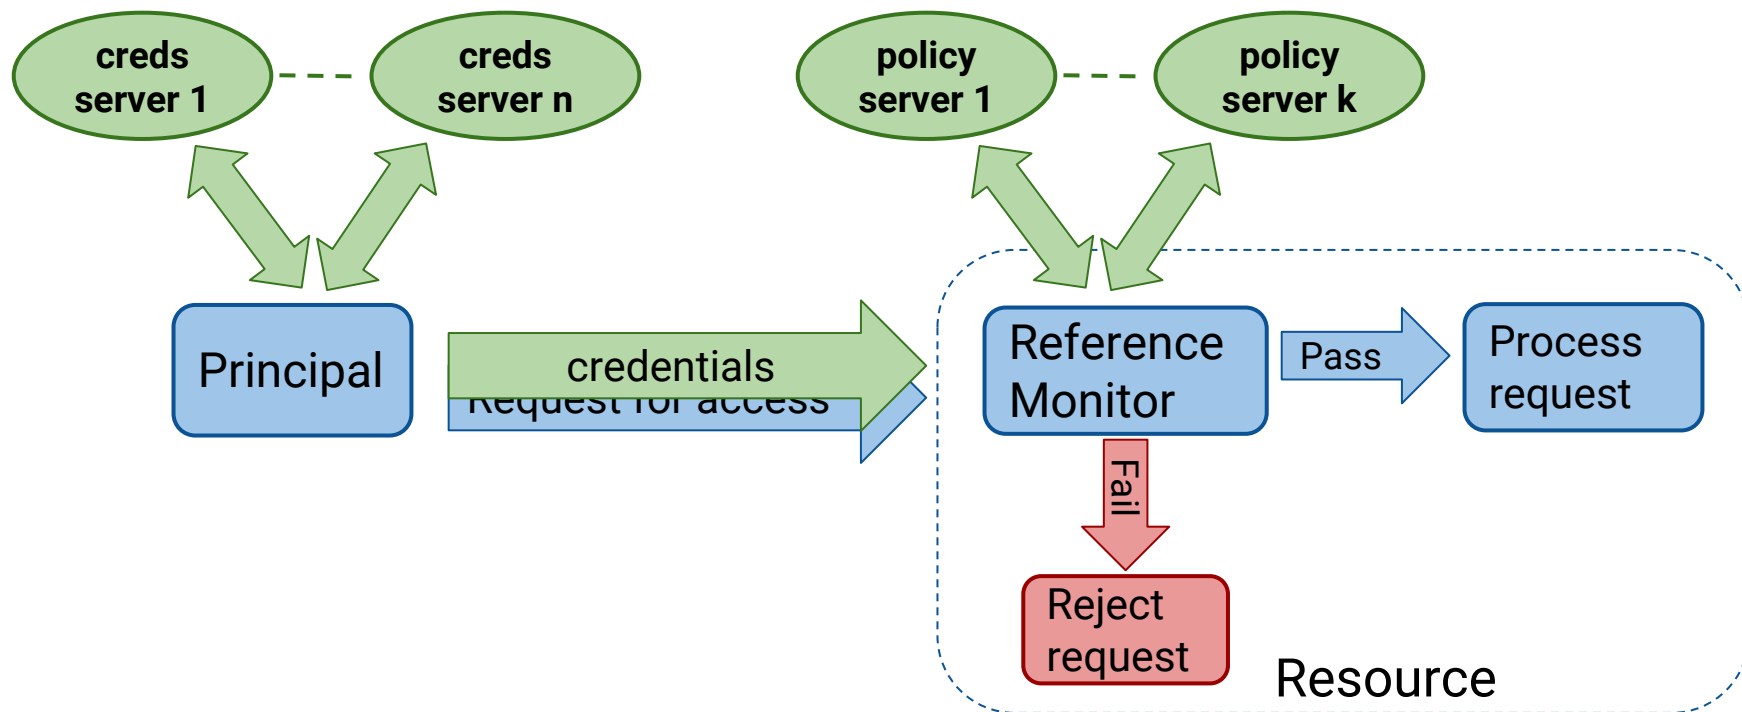

Authorization model

Distributed authorization model

Distributed authorization model

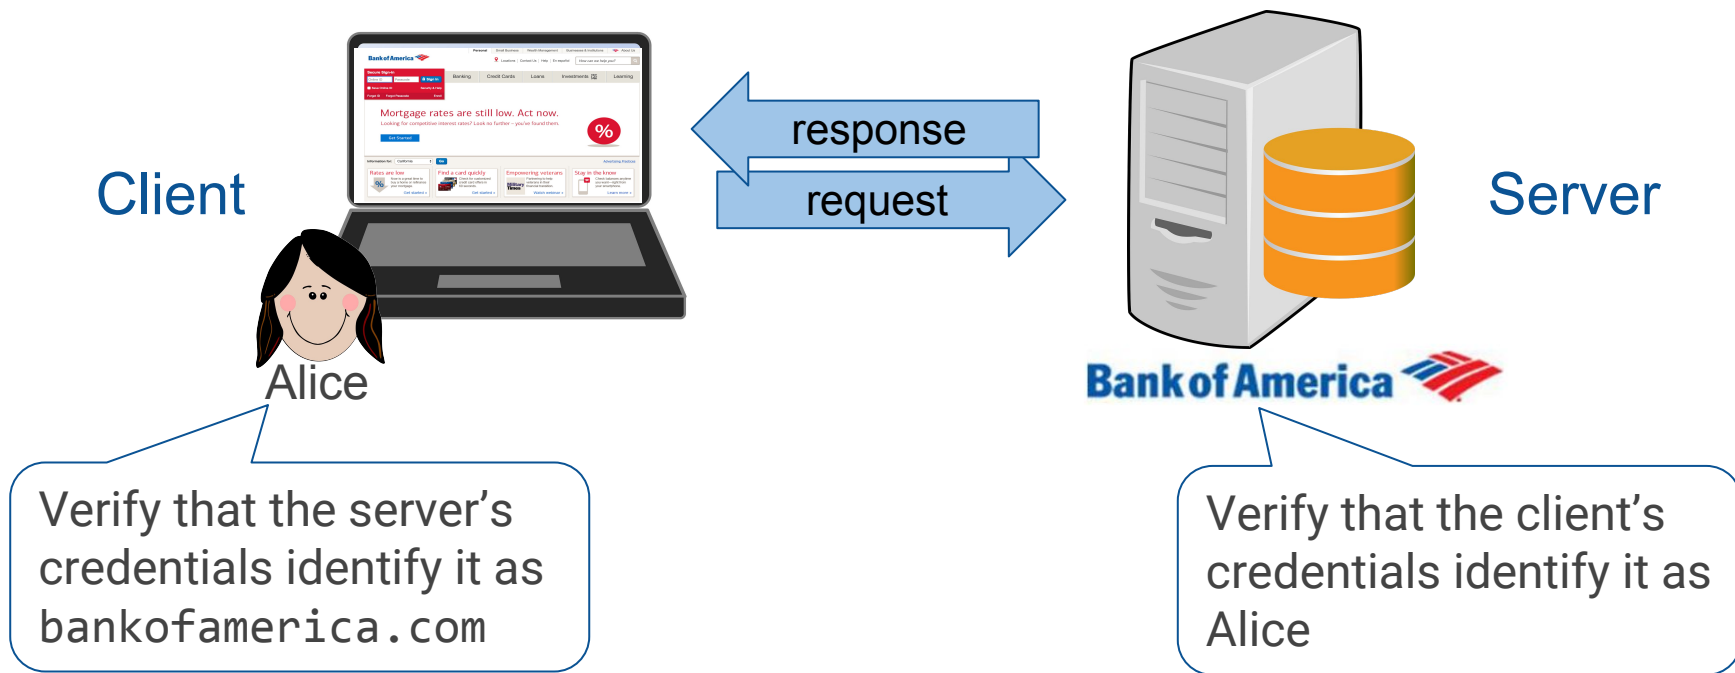

Building blocks

- Mechanisms for generating, distributing, and validating credentials
- Languages for defining access control policies
- Algorithms and logics for checking policies
- Protocols for setting up secure communication channels

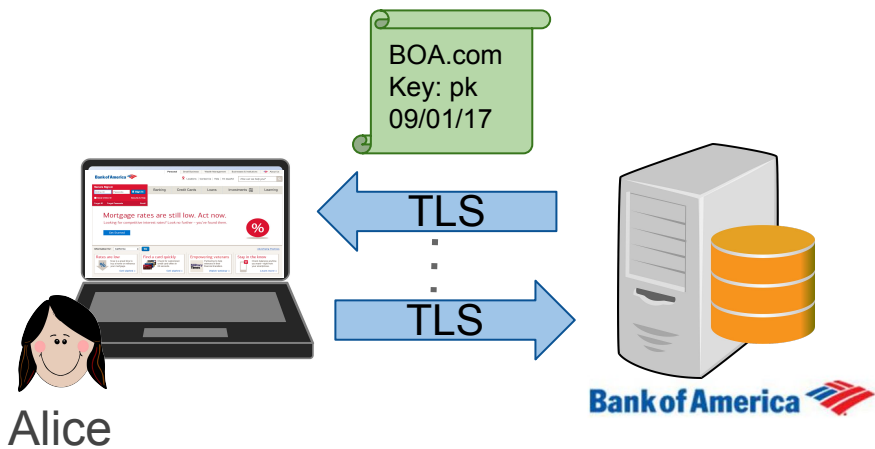

Web authorization model

Mutual authorization

Server authorization on the Web (under TLS)

TLS protocol allows clients to authorize the server and establishes an encrypted channel between them

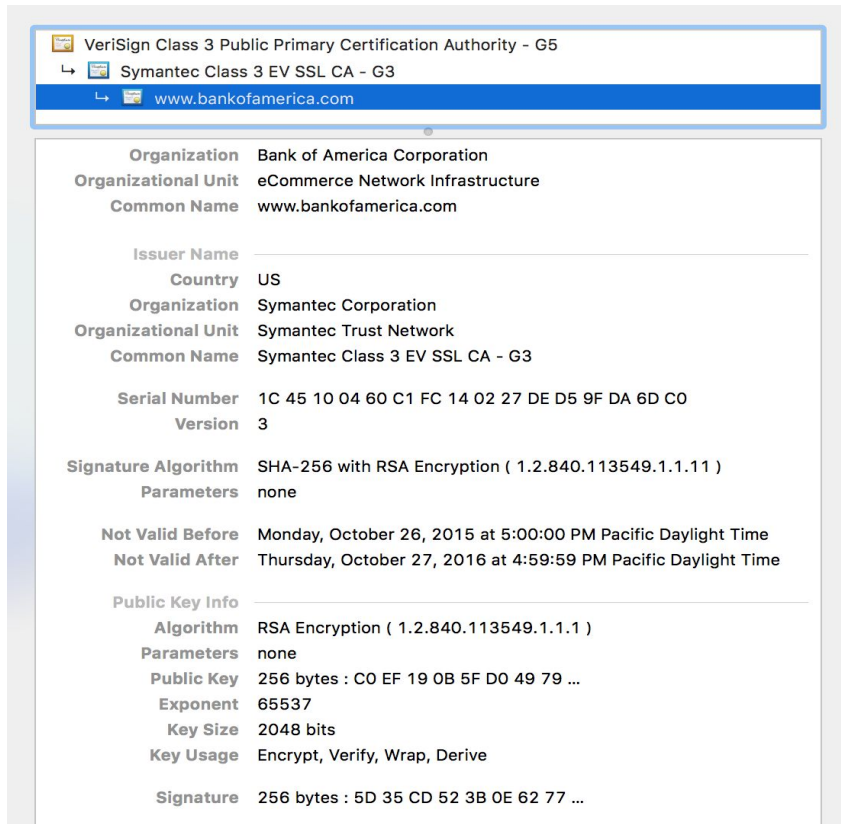

Servers possess

- a digital signature public and secret key pair (pk, sk)
 - $\forall m. \text{Verify}(pk, m, \text{Sign}(sk, m))$
- a signed **x509 certificate** binding a domain name (bankofamerica.com) to the public key pk

During TLS, the server presents its certificate to a client

Server authorization on the Web (under TLS)

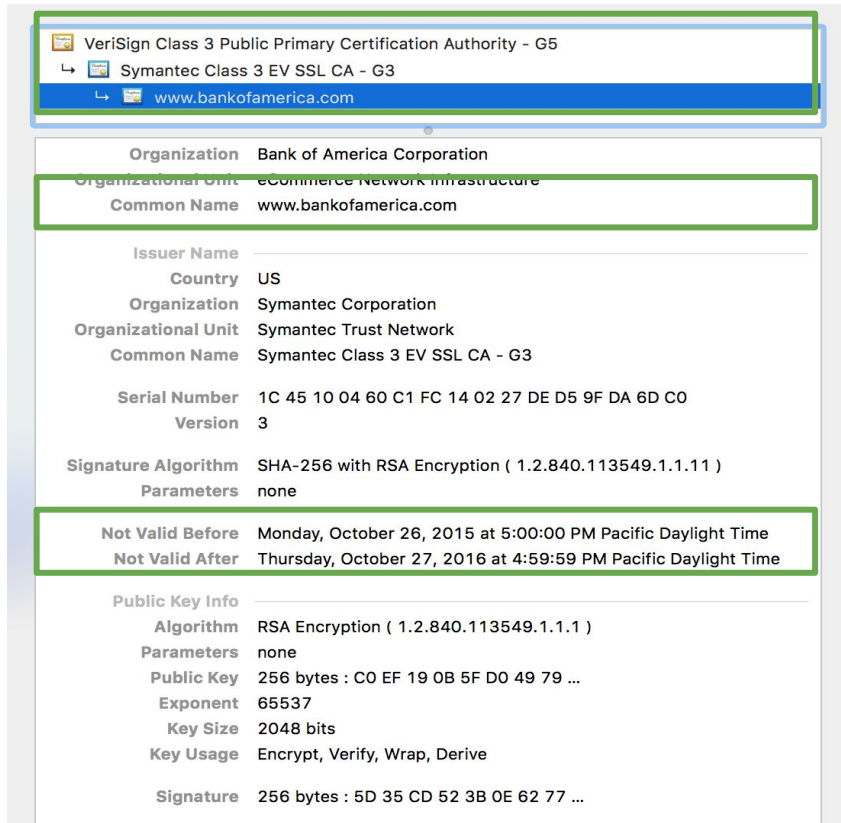

Organization	Bank of America Corporation
Organizational Unit	eCommerce Network Infrastructure
Common Name	www.bankofamerica.com
Issuer Name	
Country	US
Organization	Symantec Corporation
Organizational Unit	Symantec Trust Network
Common Name	Symantec Class 3 EV SSL CA - G3
Serial Number	1C 45 10 04 60 C1 FC 14 02 27 DE D5 9F DA 6D C0
Version	3
Signature Algorithm	SHA-256 with RSA Encryption (1.2.840.113549.1.1.11)
Parameters	none
Not Valid Before	Monday, October 26, 2015 at 5:00:00 PM Pacific Daylight Time
Not Valid After	Thursday, October 27, 2016 at 4:59:59 PM Pacific Daylight Time
Public Key Info	
Algorithm	RSA Encryption (1.2.840.113549.1.1.1)
Parameters	none
Public Key	256 bytes : C0 EF 19 0B 5F D0 49 79 ...
Exponent	65537
Key Size	2048 bits
Key Usage	Encrypt, Verify, Wrap, Derive
Signature	256 bytes : 5D 35 CD 52 3B 0E 62 77 ...

Server certificate is in the X509 format which is very expressive but hard to parse

Client verifies that the certificate

- has not expired
- has the expected domain name
- has a recognized issuer

Server authorization on the Web (under TLS)

Server certificate is in the X509 format which is very expressive but hard to parse

Client verifies that the certificate

- has not expired
- has the expected domain name
- has a recognized issuer

Web public-key infrastructure (PKI)

Hierarchical network of CAs

- Root CA certifies intermediate CAs which certify Web servers
 - Root CA certificate is **self-signed**
 - About 60 root CAs and 1200 intermediate CAs
- CAs can issue certificates for any domain
- A wrongly issued certificate can be used to impersonate a server

Browsers maintain list of trusted CAs

Recent CA compromise incidents

2014: Indian NIC (intermediate CA trusted by the Indian CCA root authority) issued unauthorized certificates for several Google domains [\[link\]](#)

Response

- Indian CCA revoked all NIC certificates
- Chrome restricted Indian CCA to 7 domains

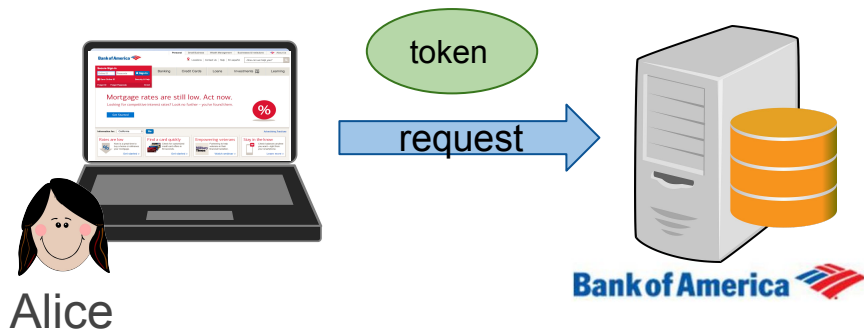

2015: MCS Holdings (intermediate CA trusted by CNNIC root authority) issued unauthorized certificates for several Google domains [\[link\]](#)

Response

- Chrome revoked the malicious certificates and stopped recognizing CNNIC as a root CA

Client authorization on the Web

Clients typically send their credentials after TLS completes and an encrypted channel is established

Credentials are mostly **bearer tokens** but have many flavors

- Username/passwords
- Cookies
- OAuth2 tokens
 - delegated by an identity provider
- Macaroons
 - delegated across multiple third-parties

Designing client credentials has been a far more creative space than server credentials

Token based authorization

Upsides:

- Simple, efficient, easy to deploy
- Tokens can be attenuated and delegated peer-to-peer (e.g., Macaroons)
- Ubiquitous on the Web, standardized with lots of implementations

Downsides:

- Roundtrip to issuer for token creation and verification
- Proliferation of tokens at clients; one per issuer

Alternate public-key infrastructures (PKI)

Decentralized approach to certification

- Pretty good privacy (PGP)
- Simple Distributed Security Infrastructure (SDSI)

Pretty Good Privacy (PGP) [Zimmerman 94]

- Framework for encrypting email
- Principals have encryption public and secret pairs, and certificates binding email address to encryption public keys
- **Web of trust:** *Egalitarian approach => anybody can sign certificates*
 - Alice may sign a certificate for her friend Bob's public key
 - Carol will recognize this certificate as long as she recognizes Alice
 - Trust grows organically rather than through a hierarchy of CAs
- Related startup: <https://keybase.io/>

Simple Distributed Security Infrastructure (SDSI)

- Also an egalitarian approach
- Principals issue certificates binding **local names** to other principals
 - e.g., Alice issues a certificate binding “friend” to Bob’s public key
- **Linked local namespaces**
 - Certificate can be linked to form chains of names
 - Alice’s TV (another principal) who refers to Alice as “Alice” may refer to Bob as “Alice’s friend”
- **Name based access control policies**
 - Alice’s TV may authorize anyone with a name matching “Alice’s friend”

Simple Distributed Security Infrastructure (SDSI)

History of SDSI

- Originally developed by Rivest and Lampson in 1996
- Later merged with Elisson's related Simple Public Key Infrastructure (SPKI), and is now jointly referred as **SPKI/SDSI**
- Followed by RFCs for standardization [2692, 2693], several academic papers providing algorithms, semantics, logics, etc.

Distributed authorization history

80s and 90s: Lots of interesting distributed authorization research

Frameworks: KeyNote, PGP, SPKI/SDSI, X509, Active certificates, Macaroons, ...

Policy languages and logic: ABLP, RT, SecPal, Binder, ...

Late 90s: Web authorization model took off

- Centralized x509 PKI for server authorization
- Various token flavors for client authorization

Last few years: Distributed authorization research is back in demand, thanks to **Internet-of-Things (IoT)**!

A collage of various technology icons (smartphone, laptop, cloud, game controller, etc.) with several instances of the 'Pepe the penguin' meme character overlaid on them.

'HACKERS REMOTELY KILL A JEEP ON THE HIGHWAY'

Top IoT Vulnerabilities

HP Study Reveals 70 Percent of Internet of Things Devices Vulnerable to Attack

[danielmiessler](#) 07-29-2014 05:09 AM - edited 07-07-2015 12:33 PM

- Insufficient authentication and authorization (80%)
- Lack of transport encryption (70%)
- Insecure web interfaces (60%)
- Insecure software updates (60%)
- Insecure defaults (70%)

Top IoT Vulnerabilities

HP Study Reveals 70 Percent of Internet of Things Devices Vulnerable to Attack

[danielmiessler](#) 07-29-2014 05:09 AM - edited 07-07-2015 12:33 PM

- Insufficient authentication and authorization (80%)
- Lack of transport encryption (70%)
- Insecure web interfaces (60%)
- Insecure software updates (60%)
- Insecure defaults (70%)

Security First: Bake in security mechanisms from the ground up

Authorization challenges for IoT

- Devices can behave both as clients and servers
- Far too many IoT devices than Web domains
 - Gartner: There will be **20 billion IoT devices by 2020** [\[link\]](#)
 - Centralized certificate mechanisms may not scale
- Fragmented ecosystem, trust relationships are more nuanced
- Limited network connectivity and bandwidth
- Very little human administration

Authorization Requirements

Summary

- Decentralized deployment
- Mutual authorization
- Fine-grained delegation
- Auditable access
- Revocation
- Ease of use

Decentralization

Decentralized deployment and peer-to-peer (p2p) communication are the main guiding principles for this work

Why?

- User privacy
- Service provider liability
- Support offline mode as a first-class citizen

Centralized models

Upsides

- Centralized access management
- Seamlessly jump across networks
- Automatic software updates
- Data storage and backups
- Account recovery

Centralized models

Downside 1: **User privacy**

- Private data leakage
- Tracking (in both digital and physical worlds)
- Growing concern all over the world
- Being taken seriously now
 - e.g., end-to-end encryption in WhatsApp and iMessage

Centralized models

Downside 2: **Service provider liability**

- Subpoenas, break-ins, insiders threats
- Secure storage of personally identifiable information (PII) is a huge pain!

Centralized models

Downside 3: **Reliance on internet connectivity**

- Loss of functionality when internet access is not available
 - e.g., devices on an airplane
 - Internet is still a luxury for a significant chunk of the world
- Fundamentally inefficient

Our objective: Decentralization

- Define an ***egalitarian*** system where any principal can become an authority for some set of other principals
 - e.g., Alice may become an authority for all her home devices
- Minimize dependence on global services, e.g., CAs, proxies, etc.
- Maximize what can be achieved via peer-to-peer interactions

Use the cloud where it offers value!

- Account Recovery

Delegate credentials to the cloud with usage restrictions

- Transparent Proxy

Run a transparent cloud service that allows jumping across networks

- Data backup

Backup a **readonly / encrypted** copy of the data in the cloud

- Distributing credentials

Setup a cloud mailbox to distribute credentials, but NOT use them

Summary

- Decentralized deployment
- Mutual authorization
- Fine-grained delegation
- Auditable access
- Revocation
- Ease of use

Mutual authorization

During any interaction, each end must verify that the other end is authorized in the context of the interaction

Mutuality is very important

Mutual authentication may be important as well depending on the audit requirements

Delegation of authority

Model must support delegation of authority between principals

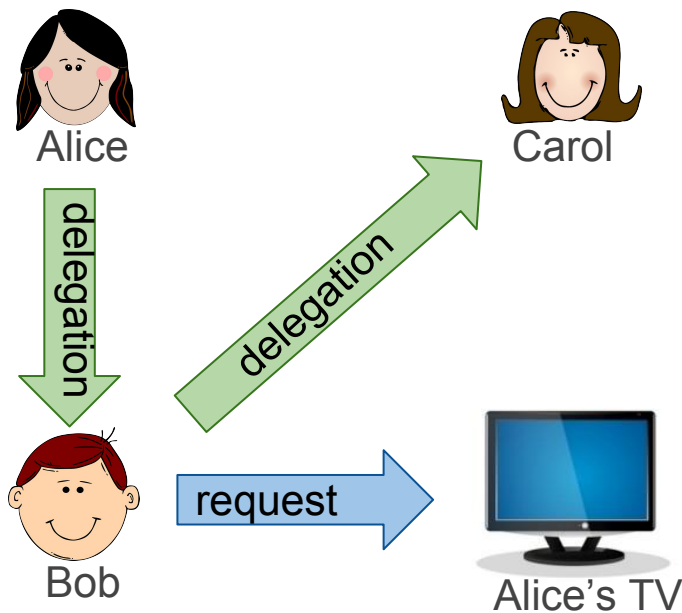

- under fine-grained constraints
 - *only until 6PM*
 - *only for this displaying photos*
 - *only when Alice is in nearby*
- across multiple hops
- in a convenient manner

Delegation of authority

Model must support delegation of authority between principals

- under fine-grained constraints
 - *only until 6PM*
 - *only for this displaying photos*
 - *only when Alice is in nearby*
- across multiple hops
- in a convenient manner

Auditable access

Principals must be able to audit the use of the delegations granted by them

Auditing is the fallback when delegation restrictions cannot be properly codified

e.g., only watch PG-13 movies on the TV

Revocation

Principals must be able to revoke previously granted delegations

- Revoke Bob's access to all of Alice's devices
- Revoke all access held by a tablet, when it gets lost or stolen

This is a hard problem, lots of trade-offs

- Instantaneous vs. eventual revocation
- Communication, computation and storage overhead
- Supporting the P2P (Offline) scenario

Ease of use

Systems with complex interfaces and mechanisms often have degraded security as users look for insecure workarounds

Therefore, authorization mechanisms must be easy to understand and use, both for end-users and system developers

Read: [Why Johnny can't encrypt?](#) (*J. D. Tygar and A. Whitten*)

Hardware constraints

IoT devices span a very wide hardware spectrum

For now, we do NOT restrict ourselves with hardware constraints

- Instead, focus on designing a general authorization architecture
- Hardware optimizations will hopefully follow

(Read: [CESEL: Securing a Mote for 20 Years](#))

Summary

- Decentralized deployment
- Mutual authorization
- Fine-grained delegation
- Auditable access
- Revocation
- Ease of use

Vanadium Authorization Model

Joint work with Asim Shankar, Gautham Thambidorai,
and Dave Presotto

What is Vanadium?

Open source, cross-platform application framework for building secure, multi-device experiences

Components

- Identity and authorization model
- RPC framework
- Naming and discovery framework
- Peer-to-peer storage

What is Vanadium?

Open source, cross-platform application framework for building secure, multi-device experiences

Components

- Identity and authorization model
- RPC framework
- Naming and discovery framework
- Peer-to-peer storage

Rest of the lecture

- Vanadium authorization model primitives
 - Identity model
 - Delegation and revocation
 - Authentication protocols
 - Access control policies
- Application: Physical lock
- Practicalities and discussion

Principal

Represented by a unique digital signature public and private key pair (P, S)

- Private key is never shared over the network
- Ideally held in a TPM on the device

Fine-grained: Each app, process, service is a different principal

- Distinguish between Alice's son Bob's tablet's Farmville app & Alice's daughter Carol's phone's Amazon app

Blessings

Each principal has a set of hierarchical human-readable strings bound to it, called ***blessings***

e.g., Alice's television (P_{TV} , S_{TV}) may have blessings:

- Alice/TV
- Samsung/Products/TV/123

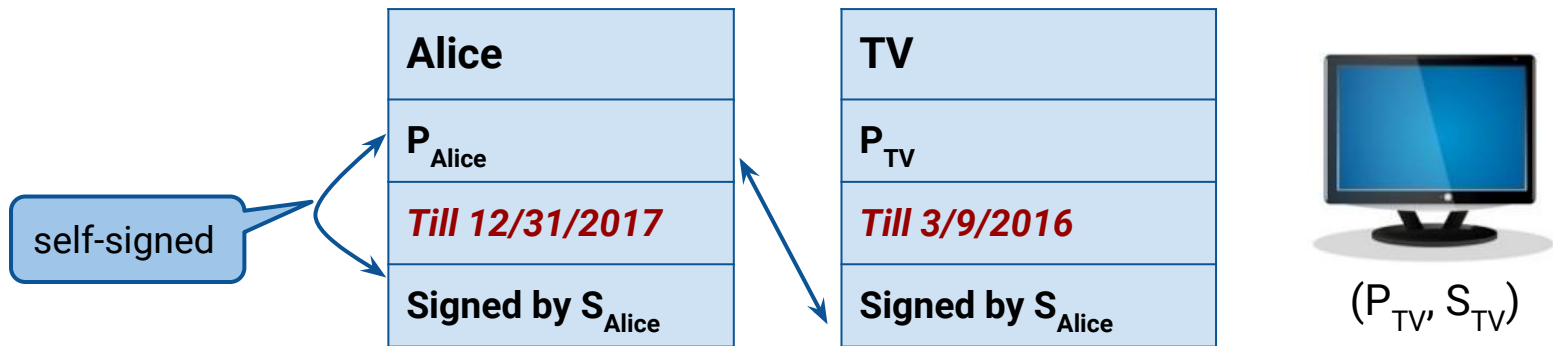

Principals are authenticated and authorized based on their blessings

e.g., Authorize all principals with blessings prefixed with Alice

Blessings

Blessings are certificate chains bound to the principal's public key

Each certificate has a Name, PublicKey, Caveats and Signature

Very simple certificate format!

The “Bless” operation

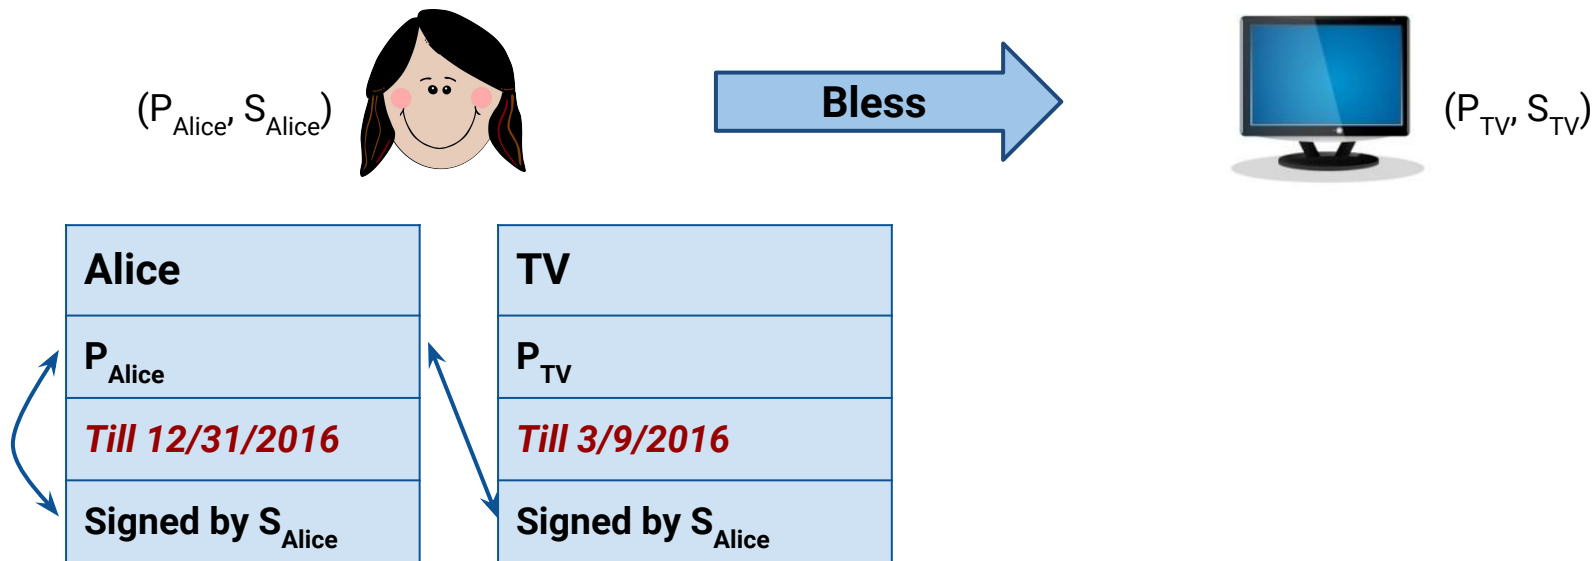

Extend one of your Blessings and bind it to another principal

	Alice
	P_{Alice}
	<i>Till 12/31/2016</i>
	Signed by S_{Alice}

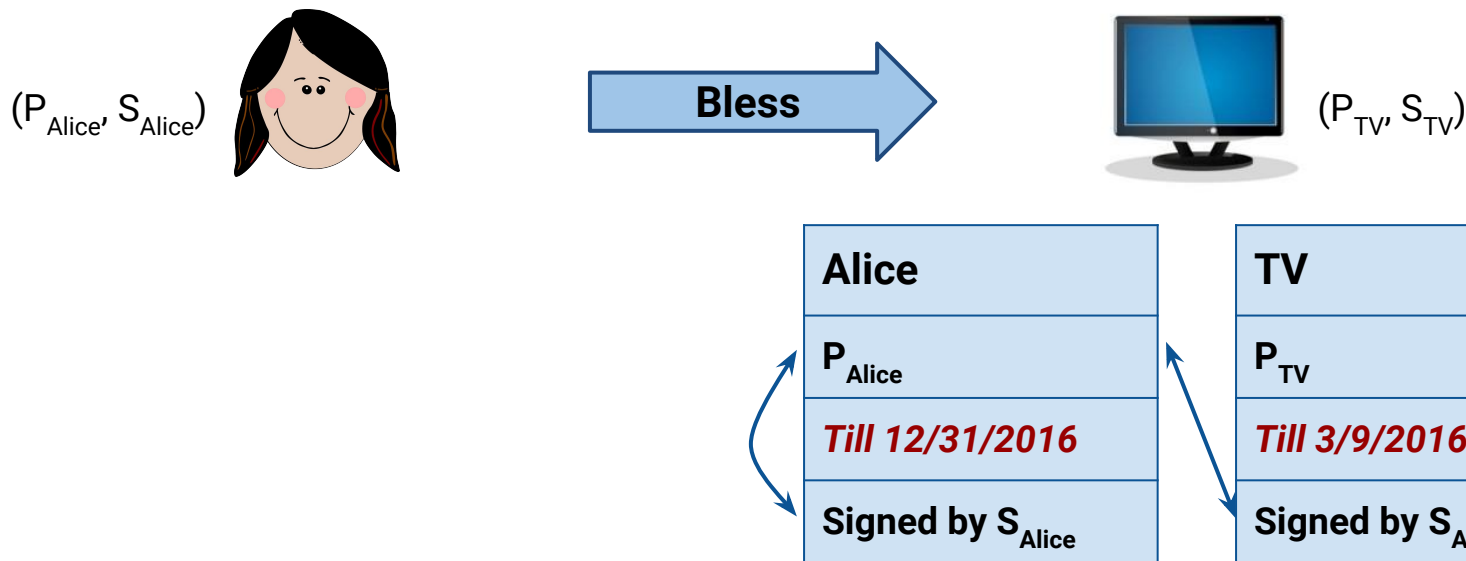

The “Bless” operation

Extend one of your Blessings and bind it to another principal

The “Bless” operation

Extend one of your Blessings and bind it to another principal

Dynamic identity creation OR Bound capability grant!

Blessings: Auditability and Binding

Blessings:

- Are bound to a private key that never leaves the device
- Can only be delegated by extending to other private keys
- Encapsulate an auditable delegation trail

Caveats

But Alice wants her TV to only access Youtube, NOT her Bank!

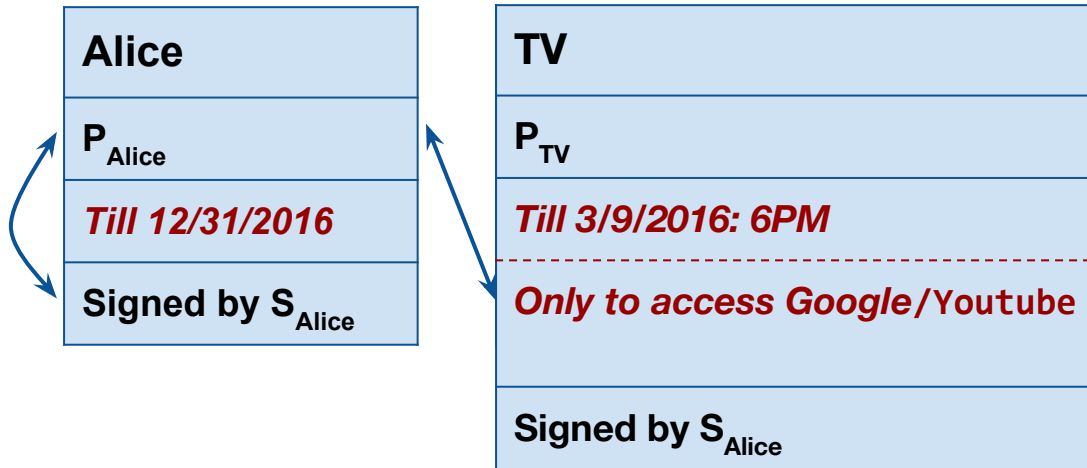

Caveats

But Alice wants her TV to only access Youtube, NOT her Bank!

Caveats

But Alice wants her TV to only access Youtube, NOT her Bank!

TV has the name *Alice/TV*

- as long as the time is before 3/9/2016: 6PM
- as long as the service being accessed is *Google/Youtube*

Caveats are powerful

Macaroons: Cookies with Caveats for Decentralized Authorization,
Politz et al., NDSS 14

Services can define their own caveats, e.g., bless the valet so that:

- valet is only authorized to drive for < 5 miles
- only for the next 3 hours
- cannot access trunk or infotainment system
- but can access GPS

Validated by the target service (first-party) when the blessing is used to make a request (first-party caveats)

Third-party Caveats

- Caveats that must be validated by a specific third-party
- Target service (first-party) only expects a “discharge” (proof) that the caveat has been validated by the specific third-party

Third-party Caveats

- Caveats that must be validated by a specific third-party
- Target service (first-party) only expects a “discharge” (proof) that the caveat has been validated by the specific third-party

Third-party Caveat

ID: <content hash>

Restriction: within 10m proximity

Loc: Alice/Proximity

Verification Key: $P_{\text{Proximity}}$

Third-party Caveats

- Caveats that must be validated by a specific third-party
- Target service (first-party) only expects a “discharge” (proof) that the caveat has been validated by the specific third-party

Third-party Caveat

ID: <content hash>

Restriction: within 10m proximity

Loc: Alice/Proximity

Verification Key: $P_{\text{Proximity}}$

Third-party Discharge

ID: <same as caveat.ID>

Caveat: for next 1 minute

Signed by $S_{\text{Proximity}}$

Mechanics

$(P_{\text{Proximity}}, S_{\text{Proximity}})$

Alice's proximity
discharger

$(P_{\text{Bob}}, S_{\text{Bob}})$

Third-party Caveat Examples

- Social networking restrictions
 - GooglePlus must assert membership in “work” circle
 - Or, must be my friend on Facebook
- Parental controls
 - Kids can watch TV only if Mom approves
 - Mom may discharge with a third-party caveat to dad!
- **Revocation**

Revocation

Revocation: Existing approaches

- Certificate revocation lists (CRLs)
 - Validating principals must periodically update CRL
 - Revocation is not instantaneous
 - CRLs tend to get large (delta-CRLs offer a reasonable fix)
- Online certificate status protocol (OCSP)
 - Onus of making OCSP queries is on the validating principal
 - Affects latency per request
 - Another vector for DOS attacks

Revocation: Existing approaches

- Recency evidence
 - “Can we eliminate certificate revocation lists?” --- Rivest 98
 - Certificate is valid only when accompanied with “recency evidence” supplied by the requestor
 - Recency evidence may be re-validated certificate or a freshly issued certificate

Revocation: Third-party caveat approach

In essence, Rivest's recency proofs idea

- Blessings carry third-party caveats specifying revocation requirements
- Caveat is discharged by a revocation service trusted by the issuer
- Requester must obtain the discharge and supply it along with the blessing

Supports instantaneous revocation

But, places a connectivity requirement on the requester

Validating Blessings

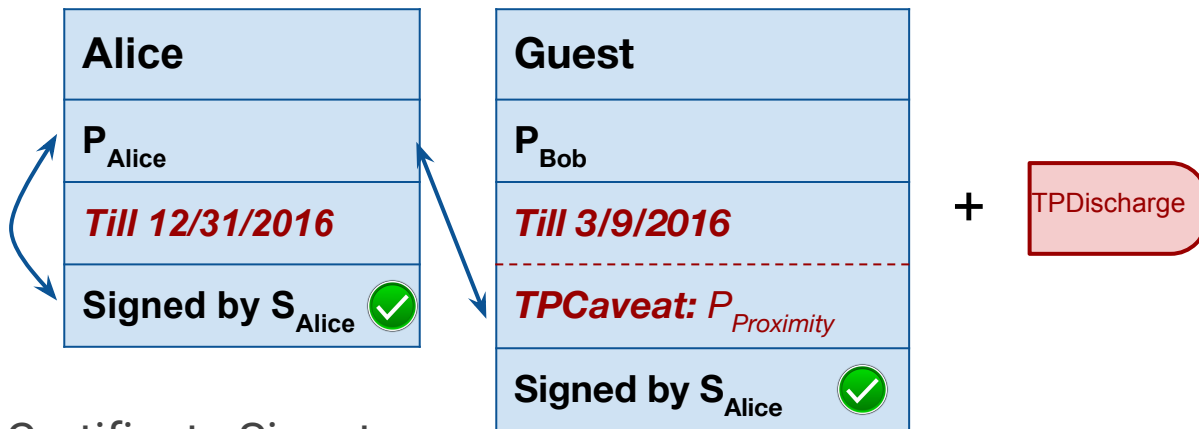

Validating blessings

How does the TV validate Bob's blessings?

Validating blessings

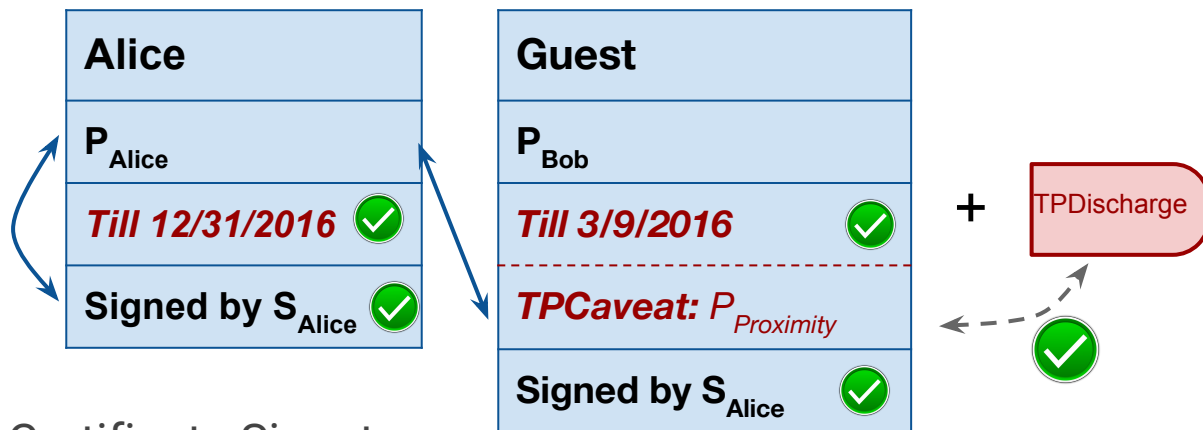

How does the TV validate Bob's blessings?

1. Verify Certificate Signatures

Validating blessings

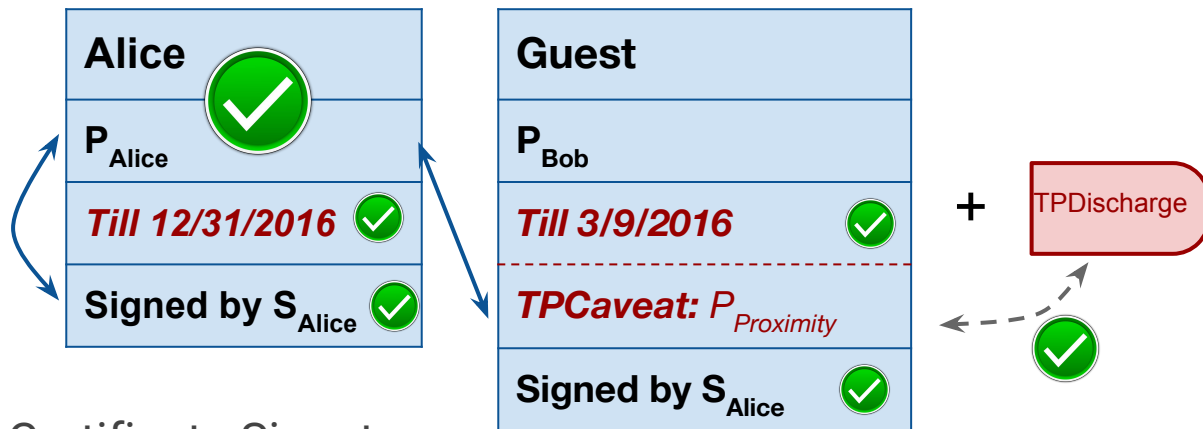

How does the TV validate Bob's blessings?

1. Verify Certificate Signatures
2. Validate all first-party and third-party caveats

Validating blessings

How does the TV validate Bob's blessings?

1. Verify Certificate Signatures
2. Validate all first-party and third-party caveats
3. Verify that the blessing root is recognized

Blessing root

The first certificate of a blessing is self-signed

Anyone can forge a blessing by creating a self-signed certificate

Alice
P Attacker
<i>Till 12/31/2016</i>
Signed by S Attacker

How do we prevent this forgery?

Blessing root

Blessing root is the name and public of the first certificate of the blessing

Principals maintain a list of recognized blessing roots

Only blessings with recognized roots are considered valid

e.g., blessing with root (P_{attacker} , Alice) is rejected by Alice's TV

Public key	Name
P_{Alice}	Alice
P_{Samsung}	Samsung

Roots recognized by
Alice's TV

Blessing root

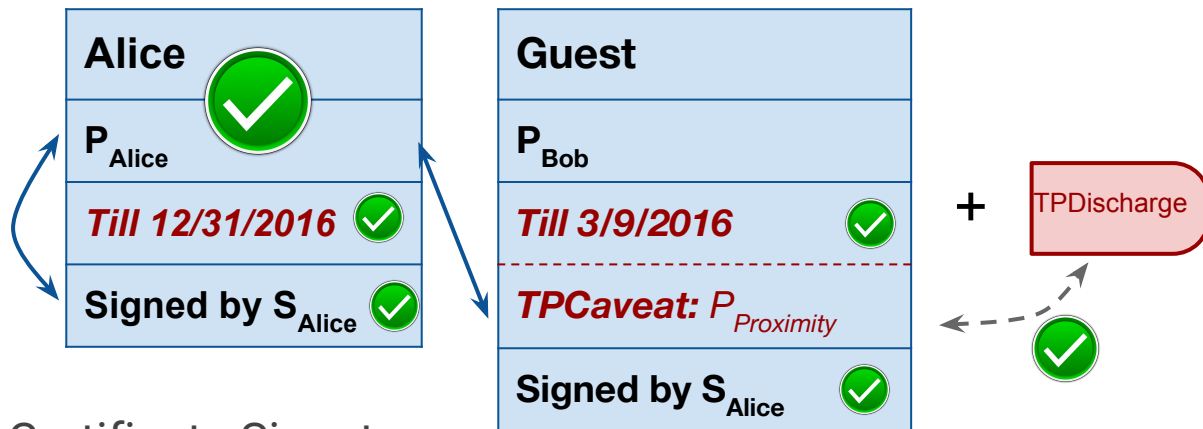

List of recognized roots is similar to the list of trusted CAs in Web browsers

But there are some key differences

- Any principal can become a blessing root
- Different principals may recognize different roots
e.g., Alice's TV may recognize $(P_{\text{Alice}}, \text{Alice})$ but Bob's TV may not
- A principal is recognized for a specific name
e.g., Alice's TV recognizes P_{Alice} for Alice and P_{Samsung} for Samsung

Validating blessings

How does the TV validate Bob's blessings?

1. Verify Certificate Signatures
2. Validate all first-party and third-party caveats
3. Verify that the blessing root is recognized

Bob can be recognized as **Alice/Guest**

Authentication and Authorization

All communication must be encrypted,
mutually authenticated and authorized

Authentication and Authorization

Client: Initiator of request

Server: Responder of request

Mutual Authentication

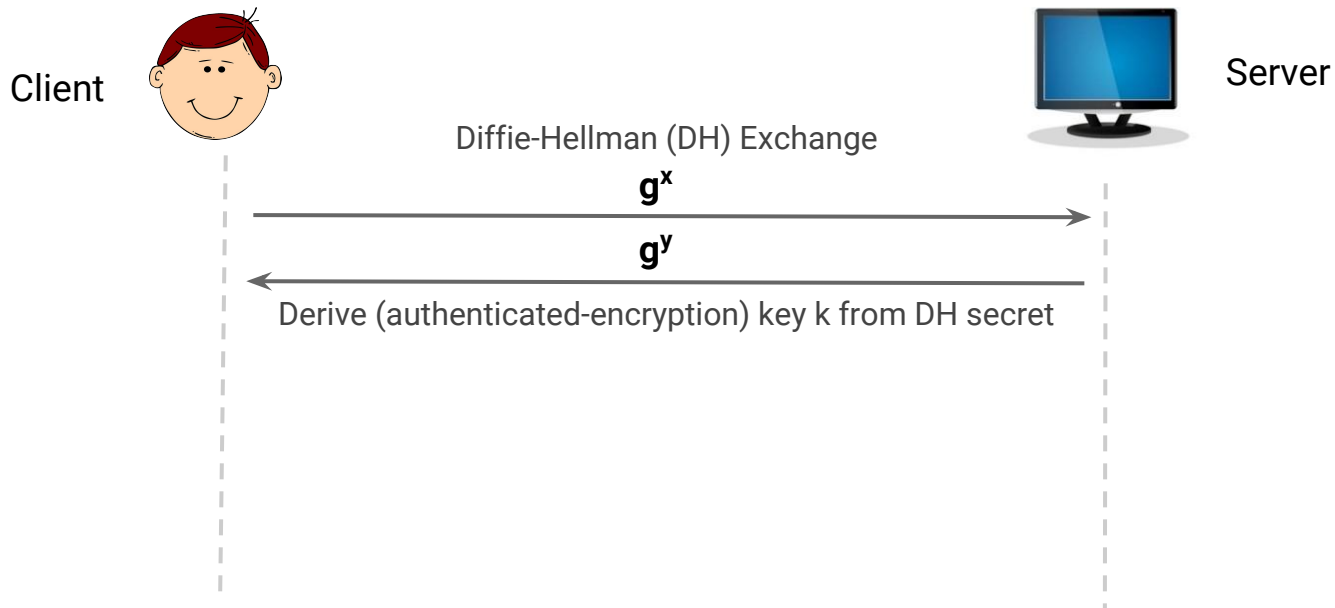

Each end learns the other end's blessings and is convinced that the other end possesses the corresponding private key

Mutual Authorization

Each end validates the other end's blessings and evaluates the blessing names against an access control policy

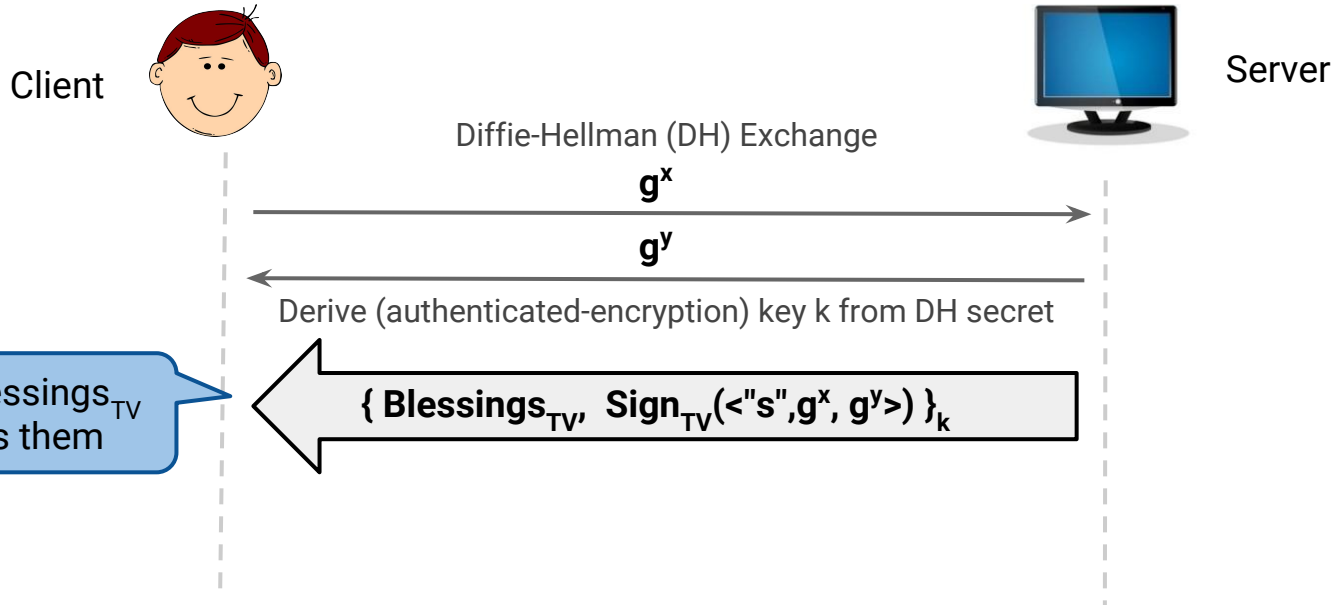

Mutual authentication protocol

SIGMA: The 'SIGn-and-MAC' Approach to Authenticated Diffie-Hellman, Krawczyk et al., CRYPTO 03

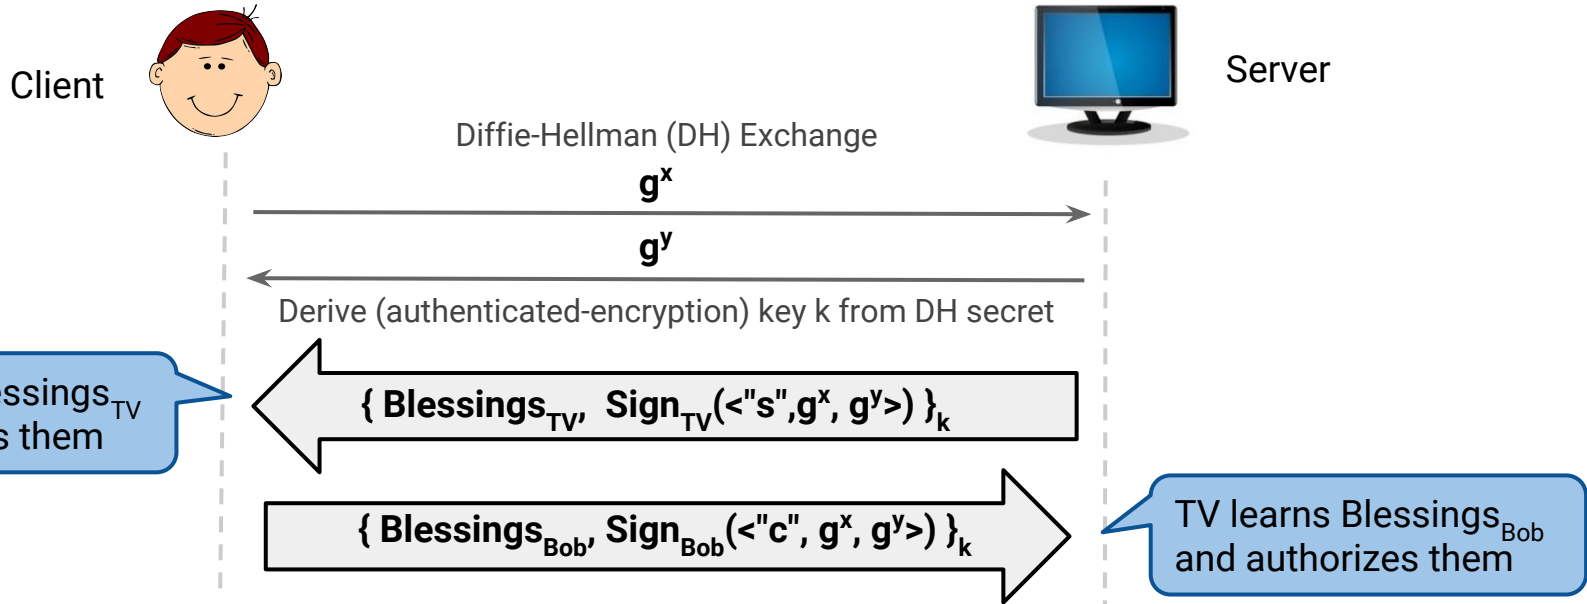

Mutual authentication protocol

SIGMA: The 'SIGn-and-MAC' Approach to Authenticated Diffie-Hellman --- Krawczyk et al., CRYPTO'03

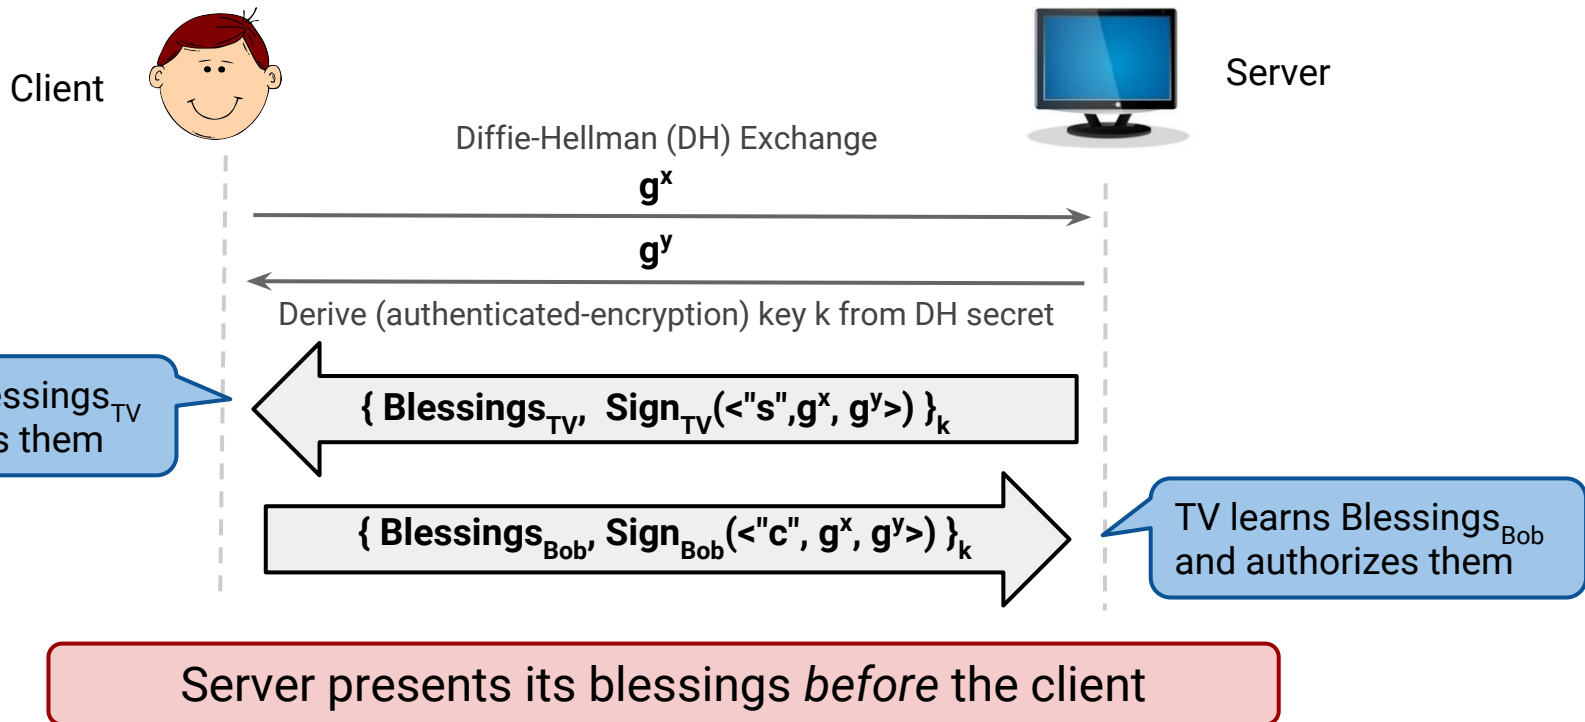

Mutual authentication protocol

Mutual authentication protocol

SIGMA: The 'SIGn-and-MAC' Approach to Authenticated Diffie-Hellman --- Krawczyk et al., CRYPTO'03

Mutual authentication protocol

SIGMA: The 'SIGn-and-MAC' Approach to Authenticated Diffie-Hellman --- Krawczyk et al., CRYPTO'03

Private mutual authentication

Neither the server nor the client wants to present its blessings first

I will only reveal
my name to *Alice/TV*

I only reveal my
name to delegates
of *Alice*

Can we resolve this deadlock?

Private Mutual Authentication

Neither the server nor the client wants to present its blessings first

I will only reveal
my name to *Alice/TV*

I only reveal my
name to delegates
of *Alice*

Can we resolve this deadlock?

Yes, using *identity-based encryption* (tomorrow's lecture)

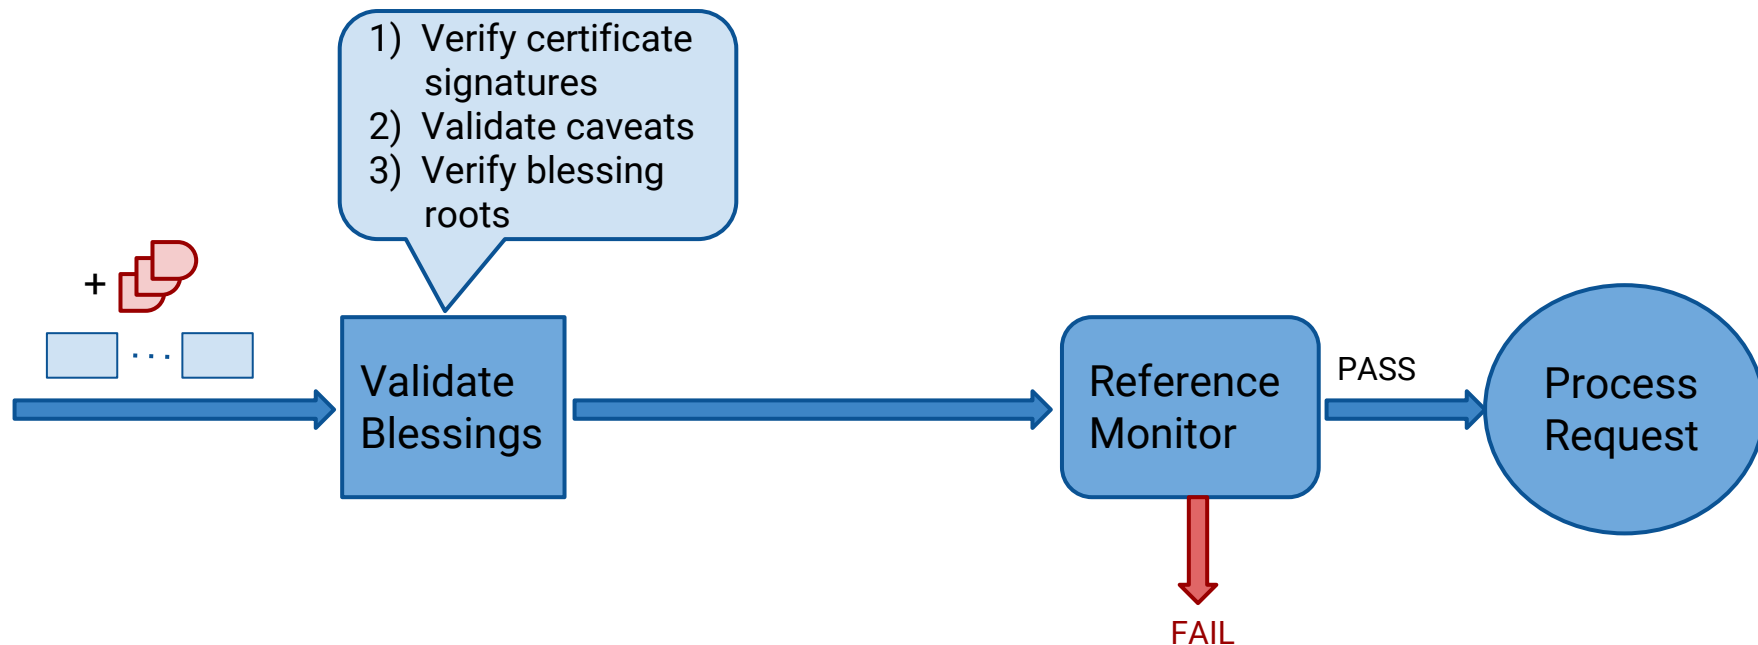

Authorization

Authorization policies are based on blessing names

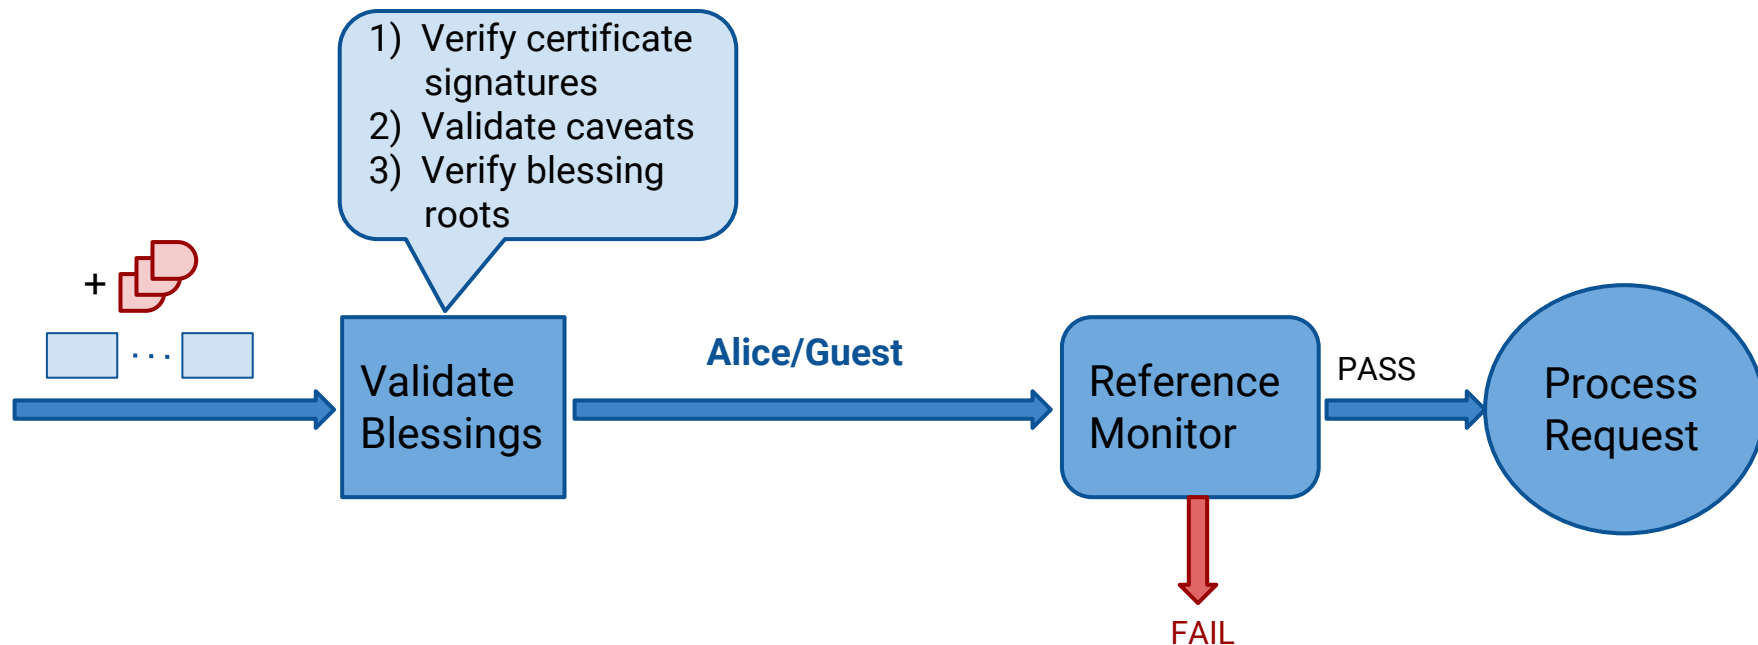

Authorization

Authorization policies are based on blessing names

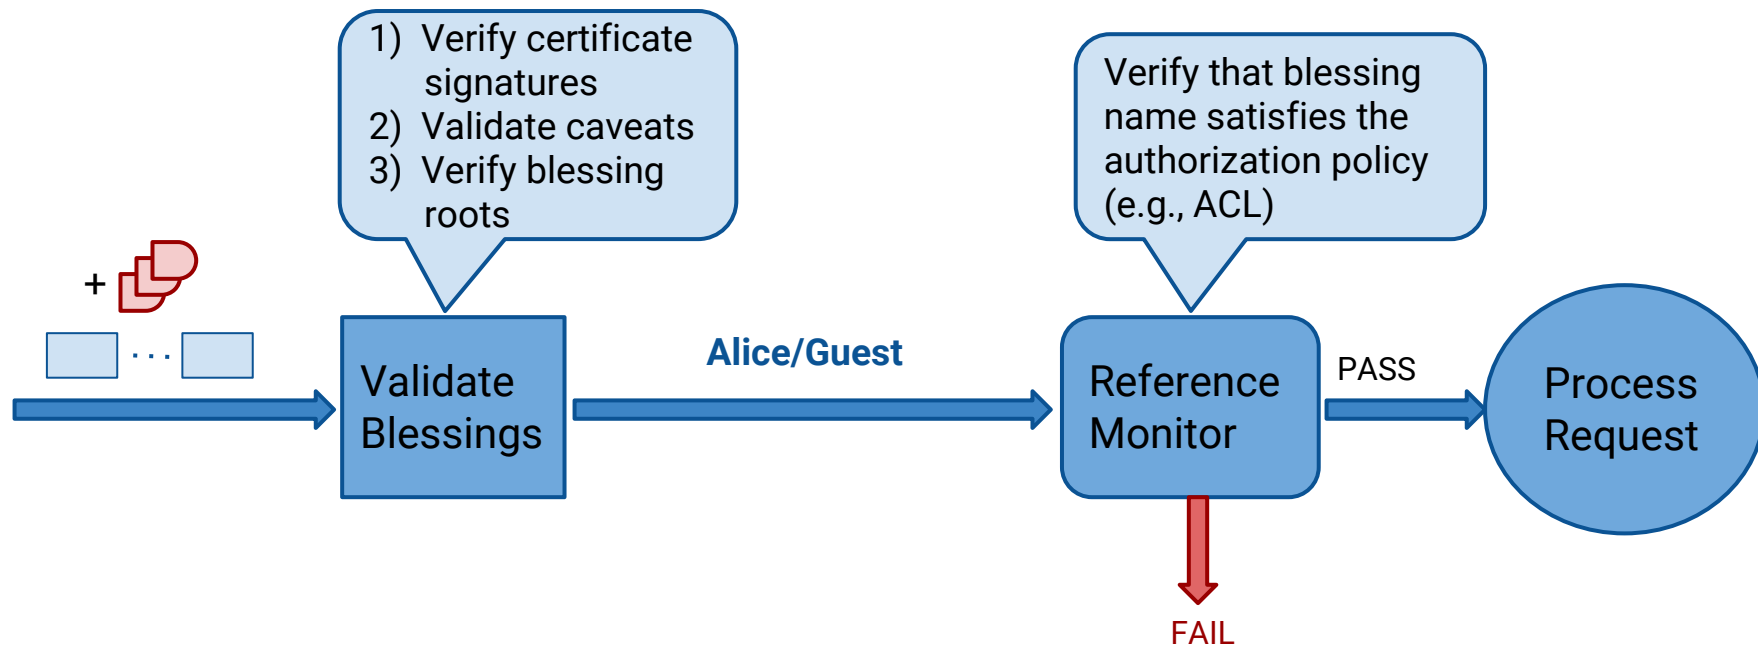

Authorization

Authorization policies are based on blessing names

Authorization

Authorization policies are based on blessing names

Access control policies

Explicitly specify set of authorized blessing names in an ACL

Policy for Alice's TV

Label	Policy
Photos	Allow: Alice
Movies	Allow: Alice/Friends

Access control policies

Explicitly specify set of authorized blessings

Policy for Alice's TV

Label	Policy
Photos	Allow: Alice
Movies	Allow: Alice/Friends

This is actually a blessing prefix and is matched by **extensions**, e.g., *Alice/Guest*, *Alice/TV/app*

(We will go over the rationale for this tomorrow)

Case Study: Physical Lock

Why Smart Locks?

- Remote locking/unlocking
- Keyless proximity-based access
- Maintain an audit log of who got in
- Mint new (virtual) keys and share with others
- Some also have a camera that will take the visitors picture

Lock setup

Lock setup

Lock setup

Properties

- **Works Offline**
No internet access required to interact with the lock
- **Fully Decentralized**
No cloud server controls access to all locks
- **Fine-grained Auditing**
Each lock device can keep track of who accessed it (plus delegation trail)
- **No bearer tokens involved**

Practicalities and discussion

Blessings Management

- Devices and apps would accumulate multiple blessings over time
- How should users visualize and grant blessings?

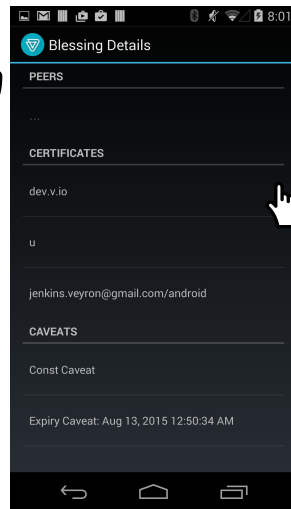

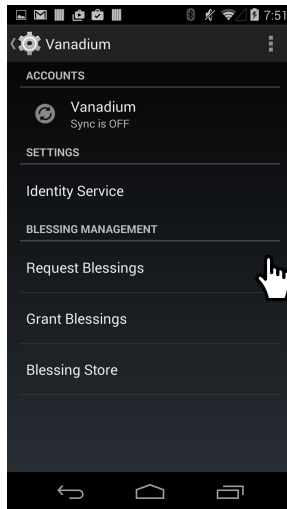

Blessings Management

- Devices and apps would accumulate multiple blessings over time
- How should users visualize and grant blessings?

Vanadium Blessings Manager App

- UI for visualizing blessings
- Grant blessings over NFC, Bluetooth

Future work: Blessing mailbox in the cloud

Private Key Management

- Securely storing private keys on device
- Many different hardware architectures and operating systems
- Multiple private keys per device (one for each app)

Private Key Management

- Securely storing private keys on device
- Many different hardware architectures and operating systems
- Multiple private keys per device (one for each app)

An Approach: Use a security agent (e.g., Plan9's factotum)

- Special process that holds private keys and performs crypto
- May store private keys in a TPM, if available
- May adjust itself based on the hardware

Vanadium authorization model: Summary

Principal and Blessings

Principal is a unique public/private key pair with human-readable names bound to it

All communication is encrypted & mutually authenticated

Forward-secrecy safe protocol, client and service identity privacy

Authorization is based on blessing names

Principals authenticated and authorized based on their blessing names

Fine-grained delegation and audit

Principals can bind an extension of their blessings to another principal under caveats

Vanadium authorization model: Summary

Principal and Blessings
